# 1 Select Clause

## 1.1 Preparatory Information

### Starter Data Types

| Data Type   | Format                                |
|-------------|---------------------------------------|
| Numeric     | Positive/Negative Integers and Floats |
| Non-numeric | Must be Enclosed In Quotations        |
| Date        | 'yyyy-mm-dd'                          |

#### **Comparison Operators**

| Operator | Description              |
|----------|--------------------------|
| =        | Equal to                 |
| <>       | Not equal to             |
| <        | Less than                |
| <=       | Less than or equal to    |
| >        | Greater than             |
| >=       | Greater than or equal to |

### 1.2 Select Clause

The SELECT clause selects and returns data from one or more tables. It must be accompanied by a FROM statement, indicating which table(s) to query from. All SQL queries must have these 2 statements.

#### 1.2.1 Selecting Columns

Select All Columns: Use keyword "ALL" or "\*" in the clause.

Select Specific Columns: Specify comma-separated list of columns to pull in the clause.

Simultaneous Calculations: You can perform operations on columns as you query them

• You can assign an alias to this column, this will change the column name to the alias name in the output. Otherwise, the new column will have its original name.

SELECT employee\_name, employee\_ID, employee\_salary \* 1.05 AS new\_salary FROM employees;

#### 1.2.2 Selecting Rows

**Select Without Duplicates:** Use the "DISTINCT" keyword after your **SELECT** statement to avoid outputting any duplicate rows.

• If you select multiple columns, DISTINCT will evaluate a combination of the column values to determine duplicates. If you want to select multiple columns, but only remove duplicates from one column, use the GROUP BY clause (3.2).

# 2 Filtering Rows/Conditions

### 2.1 Where Clause

The WHERE clause filters the returned results. It uses logic to include/exclude certain columns, based on a comparison statement(s) a.k.a predicates.

- The comparison statements must correctly reference the SQL data types (chapter: 1.1).
- This clause must immediately follow the FROM clause.

## 2.2 Limit Clause

The LIMIT clause limits the number of rows returned. You can include an optional clause, OFFSET, that will skip the offset number of rows before returning.

# 2.3 Having Clause

The HAVING clause serves the same purpose as the WHERE clause, although the latter cannot perform conditions on rows after they are grouped.

# 3 Ordering Grouping Rows

# 3.1 Ordering Rows

"ORDER BY" keyword sorts the rows returned by SELECT clause in either ascending or descending order.

You can also sort rows by giving sortation priorities to specific columns. The following will sort column\_1 in an ascending order, and then column\_1 in descending order.

```
ORDER BY
column_1 ASC,
column_2 DESC;
```

## 3.2 Grouping Rows

The "GROUP BY" keyword groups rows based on the values of 1 or more columns.

• This is useful for aggregating data by grouping rows that share common values.

The following query counts the number of records for each Pet and Breed in vet\_table. The GROUP BY clause aggregates the count in the 'Total' column.

| Pet                  | Breed   | VisitReason |
|----------------------|---------|-------------|
| Cat                  | Siamese | Check-up    |
| Cat                  | Siamese | Vaccination |
| $\operatorname{Dog}$ | Poodle  | Check-up    |

| Pet | Breed   | Total |
|-----|---------|-------|
| Dog | Poodle  | 1     |
| Cat | Siamese | 2     |

Table 1: vet\_table

Table 2: Query Result

```
SELECT Pet, Breed, COUNT(*) AS Total
FROM vet_table
GROUP BY Pet, Breed
ORDER BY Pet DESC;
```

You can now use HAVING to place conditions on the aggregate function 'COUNT(\*)' (2.3).

# 4 Aggregate Functions

The parameters of statistical functions must be a single column or expression.

The output of these functions is a single column per function.

You can rename the outputted column by using an alias.

Note: To filter for columns with an aggregate function applied, you must use the HAVING clause (2.3).

### 4.1 Count

| Parameter                    | Description   |
|------------------------------|---|
| COUNT (*)                    | Count all rows in the table                             |
| COUNT $(column\_name)$       | Count all non-null rows in the column                   |
| COUNT (DISTINCT column_name) | Count unique values in the column, excluding NULL rows. |
| ,                            |   |

Using the GROUP BY clause is especially useful when paired with the COUNT function:

From (3.2), we can see that a 'Total' column returned (using the count function), containing the count of each Pet and Breed combination.

Note: It is required to have any non-aggregate function stated within the SELECT statement to be stated within the GROUP BY statement

## 4.2 Avg & Sum

The AVG() function calculates and returns the average value or a set/column.

The SUM() function calculates and returns the average value or a set/column.

By default, AVG() and SUM() calculate using all values in the column, although, using the DISTINCT keyword would result in the calculation of unique values only. The values within the column **must** be numeric.

#### 4.3 Max & Min

The MAX() function returns the maximum value of a set/column.

The MIN() function returns the minimum value of a set/column.

The DISTINCT option is not available for MAX and MIN functions.

# 5 Advanced Operators

- 5.1 Is Null
- 5.2 Like
- 5.3 Between
- 5.4 Exists
- 5.5 In
